

# Class

Define a class named `BankAccount` with an `__init__` method that initializes two instance variables: `account_holder` and `balance`.

The class has methods like `deposit` and `withdraw`, each of which takes an amount as an argument and updates the account balance accordingly. These methods also include checks for valid input and available funds.

The `get_balance` method allows you to retrieve the account balance.

We create an Object of the `BankAccount` class called `account1` with an initial balance of \$1000.

We deposit \$500 and withdraw \$200 from the account and print the account information.
